

## Lab Exercise 9– Creating Multiple EC2 Instances with for\_each in Terraform

### Objective:

Learn how to use for\_each in Terraform to create multiple AWS EC2 instances with specific settings for each instance.

### Prerequisites:

- Terraform installed on your machine.
- AWS CLI configured with the necessary credentials.

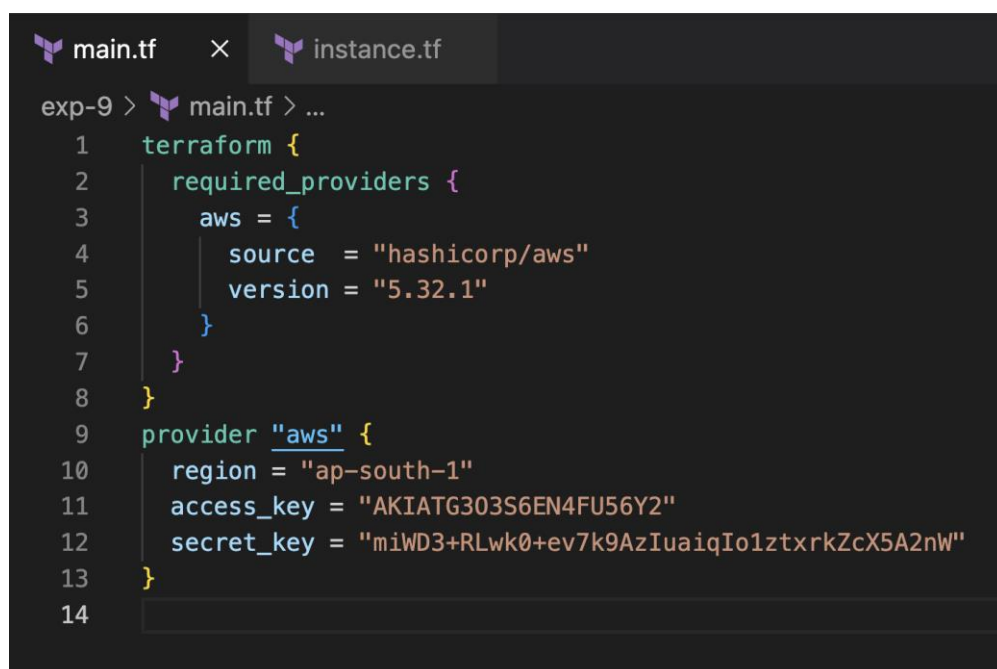

### Steps:

#### 1. Create a Terraform Directory:

```
● → Terraform-SPCM-LAB cd exp-9/  
○ → exp-9
```

- Create Terraform Configuration Files:
- Create a file named main.tf:

#### # main.tf

```
main.tf × instance.tf  
exp-9 > main.tf > ...  
1 terraform {  
2   required_providers {  
3     aws = {  
4       source = "hashicorp/aws"  
5       version = "5.32.1"  
6     }  
7   }  
8 }  
9 provider "aws" {  
10   region = "ap-south-1"  
11   access_key = "AKIATG303S6EN4FU56Y2"  
12   secret_key = "miWD3+RLwk0+ev7k9AzIuaiqIo1ztxrkJZcX5A2nW"  
13 }  
14
```

- Replace "your-key-pair-name" and "your-subnet-id" with your actual key pair name and subnet ID.
- In this configuration, we define a variable instances as a map containing settings for each EC2 instance. The aws\_instance resource is then used with for\_each to create instances based on the map.

## #instance.tf

```
exp-9 > instance.tf > ...
1  resource "aws_instance" "ec2_instances" {
2      for_each      = var.instances
3      ami           = var.instances[each.key].ami
4      instance_type = var.instances[each.key].instance_type
5      tags = {
6          Name = "EC2-Instance-${each.key}"
7      }
8  }
9  variable "instances" {
10     description = "Map of EC2 instances with settings"
11     default = {
12         "instance1" = {
13             ami           = "ami-0e670eb768a5fc3d4"
14             instance_type = "t2.micro"
15         },
16         "instance2" = {
17             ami           = "ami-0e670eb768a5fc3d4"
18             instance_type = "t2. micro "
19         },
20         "instance3" = {
21             ami           = "ami-0e670eb768a5fc3d4"
22             instance_type = "t2. micro "
23         }
24     }
25 }
26
```

## 2. Initialize and Apply:

- Run the following Terraform commands to initialize and apply the configuration:

```

● → exp-9 terraform init

Initializing the backend...

Initializing provider plugins...
- Finding hashicorp/aws versions matching "5.32.1"...
- Installing hashicorp/aws v5.32.1...
- Installed hashicorp/aws v5.32.1 (signed by HashiCorp)

Terraform has created a lock file .terraform.lock.hcl to record the provider
selections it made above. Include this file in your version control repository
so that Terraform can guarantee to make the same selections by default when
you run "terraform init" in the future.

Terraform has been successfully initialized!

You may now begin working with Terraform. Try running "terraform plan" to see
any changes that are required for your infrastructure. All Terraform commands
should now work.

If you ever set or change modules or backend configuration for Terraform,
rerun this command to reinitialize your working directory. If you forget, other
commands will detect it and remind you to do so if necessary.
○ → exp-9 █

```

- Terraform will prompt you to confirm the creation of EC2 instances. Type yes and press Enter.

```

● → exp-9 terraform apply
aws_instance.ec2_instances["instance1"]: Refreshing state... [id=i-09fae684ad310a593]

Terraform used the selected providers to generate the following execution plan. Resource actions are
indicated with the following symbols:
+ create

Terraform will perform the following actions:

# aws_instance.ec2_instances["instance2"] will be created
+ resource "aws_instance" "ec2_instances" {
  + ami                    = "ami-0e670eb768a5fc3d4"
  + arn                   = (known after apply)
  + associate_public_ip_address = (known after apply)
  + availability_zone       = (known after apply)
  + cpu_core_count         = (known after apply)
  + cpu_threads_per_core   = (known after apply)
  + disable_api_stop       = (known after apply)
  + disable_api_termination = (known after apply)
  + ebs_optimized          = (known after apply)
  + get_password_data      = false
  + host_id                = (known after apply)
}

```

```

Do you want to perform these actions?
  Terraform will perform the actions described above.
  Only 'yes' will be accepted to approve.

Enter a value: yes

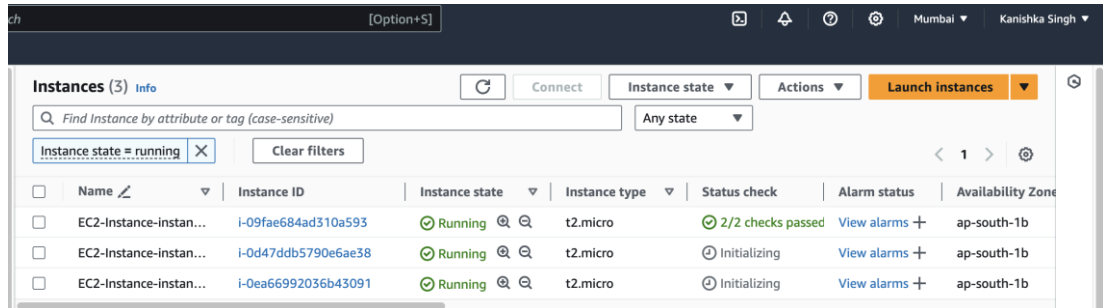

aws_instance.ec2_instances["instance2"]: Creating...
aws_instance.ec2_instances["instance3"]: Creating...
aws_instance.ec2_instances["instance3"]: Still creating... [10s elapsed]
aws_instance.ec2_instances["instance2"]: Still creating... [10s elapsed]
aws_instance.ec2_instances["instance2"]: Still creating... [20s elapsed]
aws_instance.ec2_instances["instance3"]: Still creating... [20s elapsed]
aws_instance.ec2_instances["instance2"]: Creation complete after 26s [id=i-0d47ddb5790e6ae38]
aws_instance.ec2_instances["instance3"]: Creation complete after 26s [id=i-0ea66992036b43091]

Apply complete! Resources: 2 added, 0 changed, 0 destroyed.
○ → exp-9 █

```

### 3. Verify Instances in AWS Console:

- Log in to the AWS Management Console and navigate to the EC2 service.
- Verify that the specified EC2 instances with the specified names and settings have been created.

## 4. Update Instance Configuration:

- If you want to modify the EC2 instance configuration, update the main.tf file with the desired changes.
- Rerun the terraform apply command to apply the changes:

```

exp-9 terraform apply
aws_instance.ec2_instances["instance1"]: Refreshing state... [id=i-09fae684ad310a593]
aws_instance.ec2_instances["instance3"]: Refreshing state... [id=i-0ea66992036b43091]
aws_instance.ec2_instances["instance2"]: Refreshing state... [id=i-0d47ddb5790e6ae38]

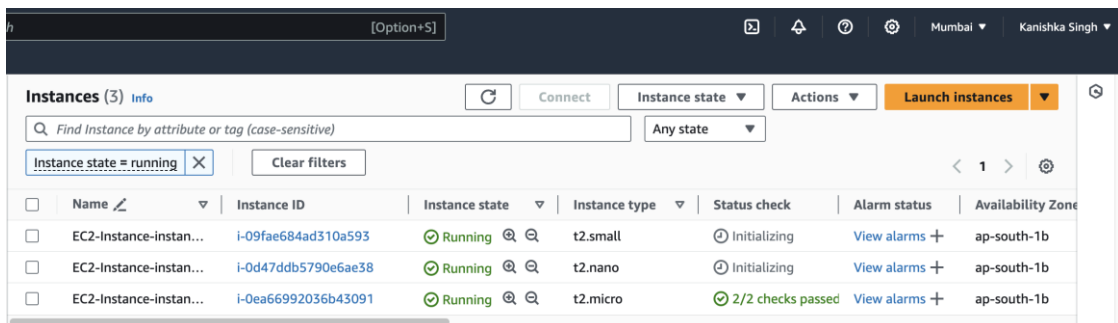

Terraform used the selected providers to generate the following execution plan. Resource actions are indicated with the following symbols:
  ~ update in-place

Terraform will perform the following actions:

# aws_instance.ec2_instances["instance1"] will be updated in-place
~ resource "aws_instance" "ec2_instances" {
  id           = "i-09fae684ad310a593"
  ~ instance_type = "t2.micro" -> "t2.small"
  tags         = {
    "Name" = "EC2-Instance-instance1"
  }
  # (30 unchanged attributes hidden)

  # (8 unchanged blocks hidden)
}

```

## 5. Clean Up:

- After testing, you can clean up the EC2 instances:

```

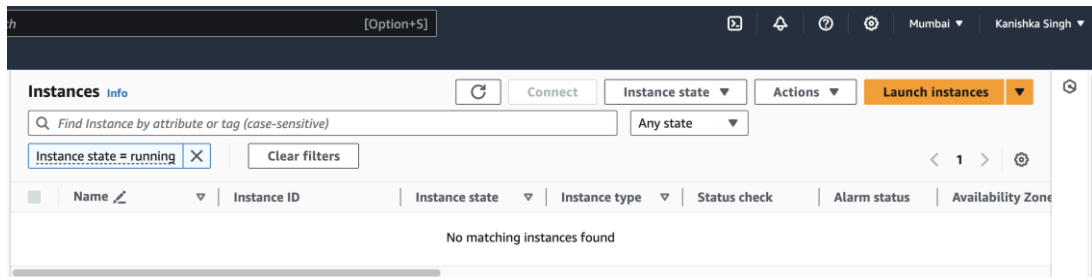

• → exp-9 terraform destroy
aws_instance.ec2_instances["instance2"]: Refreshing state... [id=i-0d47ddb5790e6ae38]
aws_instance.ec2_instances["instance1"]: Refreshing state... [id=i-09fae684ad310a593]
aws_instance.ec2_instances["instance3"]: Refreshing state... [id=i-0ea66992036b43091]

Terraform used the selected providers to generate the following execution plan. Resource
indicated with the following symbols:
  - destroy

Terraform will perform the following actions:

# aws_instance.ec2_instances["instance1"] will be destroyed
- resource "aws_instance" "ec2_instances" {
  - ami                    = "ami-0e670eb768a5fc3d4" -> null
  - arn                    = "arn:aws:ec2:ap-south-1:220886439816:inst
10a593" -> null
  - associate_public_ip_address = true -> null
  - availability_zone          = "ap-south-1b" -> null
  - cpu_core_count              = 1 -> null
  - cpu_threads_per_core        = 1 -> null
  - disable_api_stop            = false -> null
  - disable_api_termination    = false -> null

```

- Confirm the destruction by typing yes.

## 6. Conclusion:

This lab exercise demonstrates how to use the `for_each` construct in Terraform to create multiple AWS EC2 instances with specific settings for each instance. The use of a map allows you to define and manage settings for each instance individually. Experiment with different instance types, AMIs, and settings in the `main.tf` file to observe how Terraform provisions resources based on your configuration.
